

Supplement of

Diverse phenotypes of Late Glacial–Early Holocene downy birch (*Betula pubescens* Erh.) and the morphology of early Preboreal tree stands in southern Schleswig-Holstein

Supplementary material

Macrofossil data by Hartmut Usinger is provided in table S1-S5.

Location Hasenmoor	-	N 54.312108, E 9.934099
Location Kirchmoor	-	N 54.223851, E 10.064958
Location Krögensmoor	-	N 54.407600, E 9.888869
Location Ruchmoor	-	N 54.415852, E 9.719514
Location Stauner Moor	-	N 54.413441, E 10.049310

In each individual case the depth refers to depth below the bog surface. The age estimate is based on pollen stratigraphy and refers to regional biostratigraphic terms (Krüger et al., 2020).

Legend to the macrofossils schedules:

MEI/D1	- (biostratigraphic) Meiendorf/ Dryas 1 period
AL	- (biostratigraphic) Allerød period
D3	- (biostratigraphic) Dryas 3 period
PB	- (biostratigraphic) Preboreal period
BO	- (biostratigraphic) Boreal period
AT	- (biostratigraphic) Atlantic period
SB	- (biostratigraphic) Subboreal period
postgl.	- postglacial period (undefined)
x	- macrofossil present (unquantified)
p	- macrofossil present (semi-quantified)
a	- macrofossil abundant (semi-quantified)

Migration of *Betula* species into the study area

The article gives special reference to *Betula pubescens*. However, in the course of the Lateglacial and the Early Holocene the migration of different *Betula* species occurred. These different *Betula* species had different shares in the composition of the vegetation on a diachronic scale. Thus, when focusing on *Betula pubescens* only, it is important to distinguish between the different present *Betula* species in the region. Palynologically this is either hardly possible (e.g. between *B. pubescens* and *B. pendula*) or often not performed (*B. pubescens* and *B. nana*). It follows that pollen studies of the Lateglacial and early Holocene in Schleswig-Holstein mainly only classify *Betula* pollen on genus level. As a further complication, different species names and name renewals for different *Betula* species occur in the literature.

Betula species that are proven to be present during the Lateglacial and Early Holocene based on macrofossil data across the study region are dwarf birch (*Betula nana*), downy birch (*B. pubescens*) and silver birch (*B. pendula*). However, the migration of the latter occurred most probably exclusively in the course of the early Holocene (Krüger et al., 2020; Usinger, 1981b, a; Usinger and Wolf, 1982). *Betula pubescens* ssp. *tortuosa* that is recorded in different datasets can be regarded as resulting from hybridisation between *B. pubescens* and *B. nana* (Karlsson and Weih, 1996). Furthermore, works of Schütrumpf (1937, 1943, 1955) in the focus area document finds of *B. verrucosa* – a synonymous species name for *B. pendula*, which only expanded in the area from the Preboreal period onwards as a result of increasing temperature. The earliest proven presence of *Betula pubescens* of the Lateglacial in the Nahe palaeolake record dates to 13.770 cal BP (Krüger et al., 2020) and, hence, 2000 years prior to the period of investigation.

To conclude: *Betula pubescens* is present in the study area prior to the studied time interval and remains being present until today. *Betula nana* is present in the study area since shortly after deglaciation, throughout the Lateglacial and into the early Holocene. *Betula pendula* is present in the study area only by the beginning of the Holocene but the timing of its first appearance in the Early Holocene is unknown.

supplementary figures

The pictures are taken in growth favoring locations for *Betula pubescens* in different places of southern Greenland (see 3.1 Fieldwork) by the author. They underline how stands of *Betula pubescens* could have formed a barrier in the landscape and illustrate the predominantly occurring multi-branched growth-form in *Betula pubescens* stands.
